

Annex One

Quantitative Analysis of Grassland Vegetation in Bhutan

Tshuchida (1987, 1991) described grassland communities over a wide range of environments. He used Numata's Summed Dominance Ratio (SDR) to estimate the relative importance of a particular species (Numata, 1991). The observations made by Tsuchida were summarised by combining observations from similar elevations and are presented in the tables below.

Table A1: Plant communities at locations below 1000m, including those species unique to each site, along with SDR cover classes (adapted from Tsuchida 1987, 1991)

Species	Phunsholling 350m (3 sites)		Gaylephu 350m (3 sites)		Lingmethang 700-720m (5 sites)	
	SDR (%) ¹	Sites ²	SDR (%)	Sites	SDR (%)	Sites
<i>Chrysopogon aciculatus</i>	47.3	2	18.3	1	20	1
<i>Paspalum scrobiculatum</i>			88.3	3	25	3
<i>Desmodium heterocarpon</i>	42.7	2	26.7	2	3.6	1
<i>Eragrostis tenella</i>	24.0	2	26.0	2	3.4	1
<i>Cynodon dactylon</i>			47.0	3	26	5
<i>Ageratum conyzoides</i>	14.0	2	23.7	3	4	1

Annex Two

Species Tested for Use as Fodder

Tables A6 to A8 show the grass, legume and other species tested for use as fodder and the stage of testing. The stages of testing reflected are: initial testing in observation nurseries in research station plots; on-farm testing of material that performs well; and promotion of suitable material in the extension programme.

The references referred to are 1 - Roder 1983c ; 2 - AHD 1990; 3 - Rumball 1990; 4 - RNR-RC Jakarta 1997c; 5 - Roder 1982c; 6 - Gibson 1989b; 7 - RNR RC-Jakarta 1998; 8 - RNR RC-Jakarta 1997d
